

# IONS Sonde Data in Relation to Meteorological Features

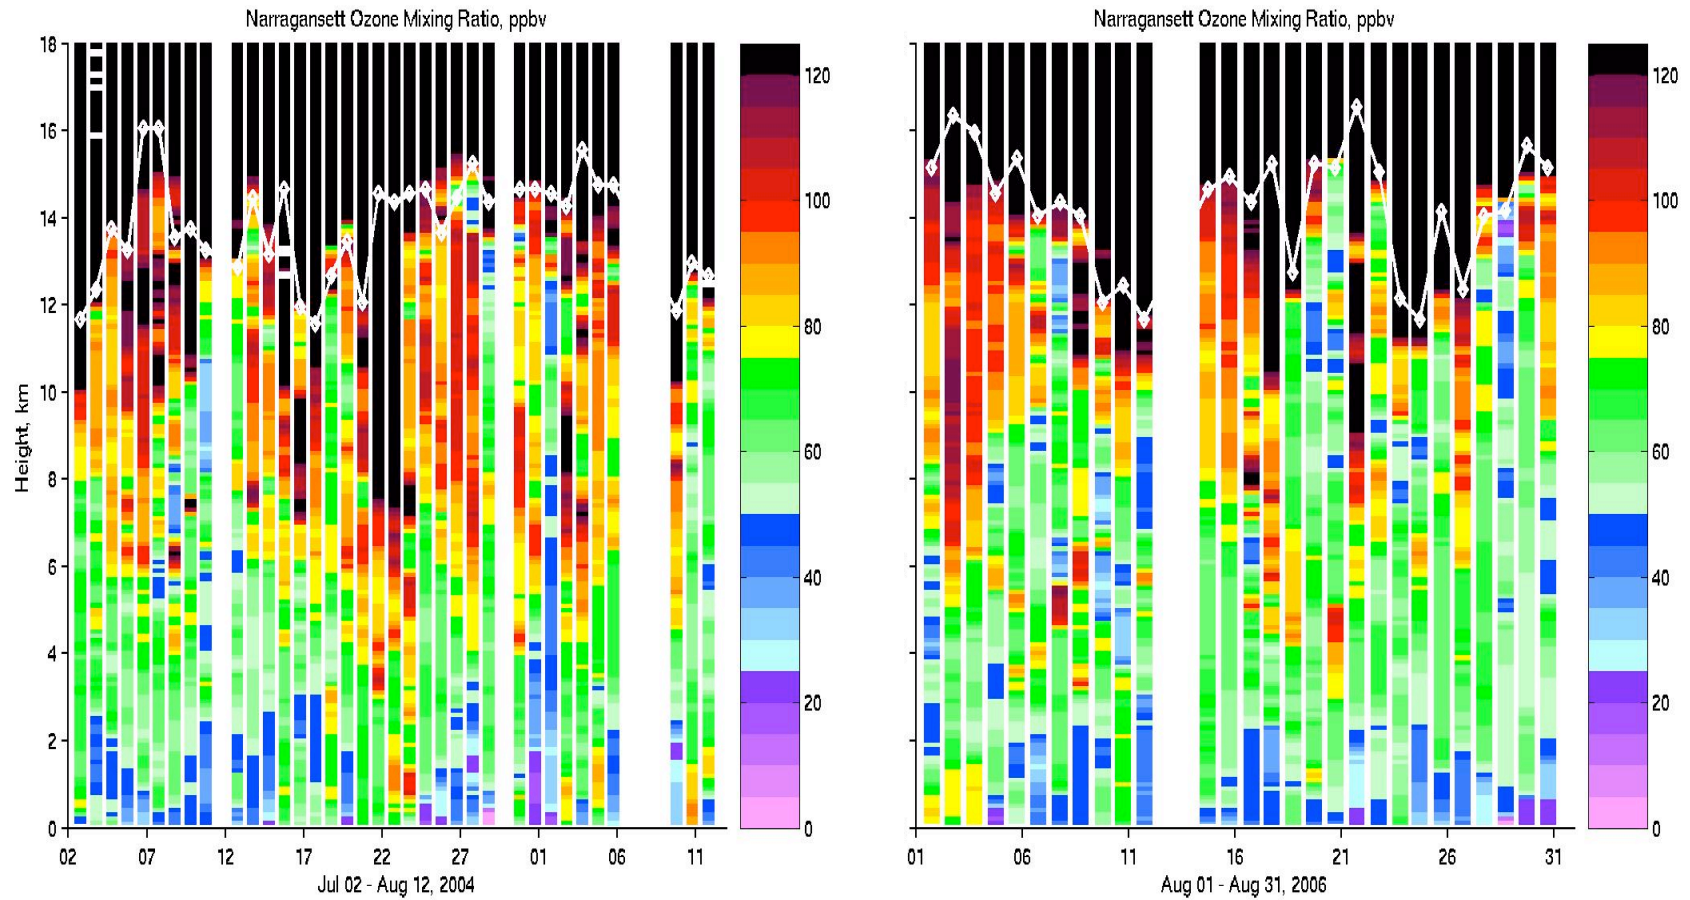

John Merrill  
University of Rhode Island

# Height:Time section - slice; stripe; band

- Vertical averages (100 m) shown here.
- Smoothing only in fill color bands. No interpolation.
- Data shown at mid-profile time. Slice gaps denote separation.

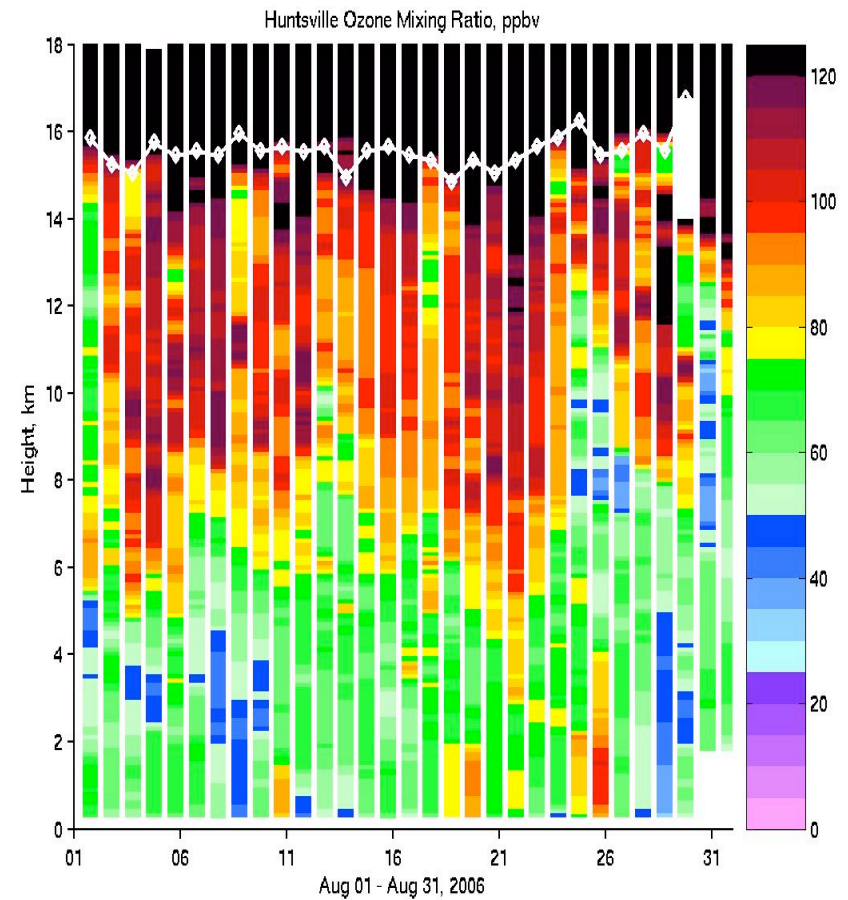

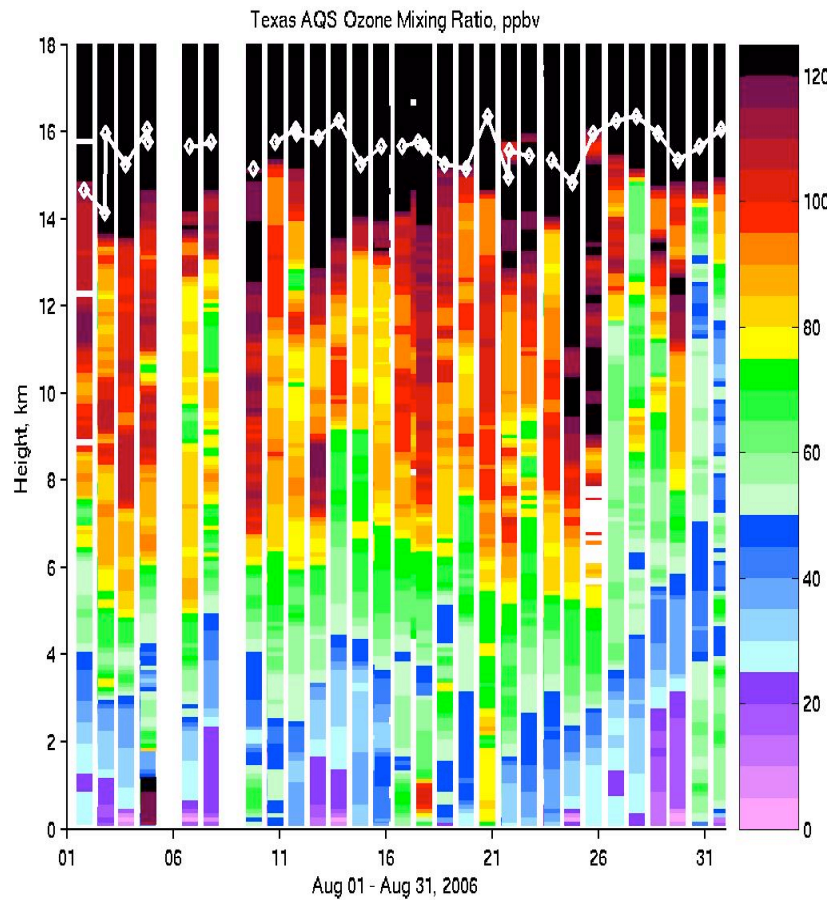

# Contrast of IONS 06/IONS 04 at one site

3/21/2007

IONS 2007 Data Workshop

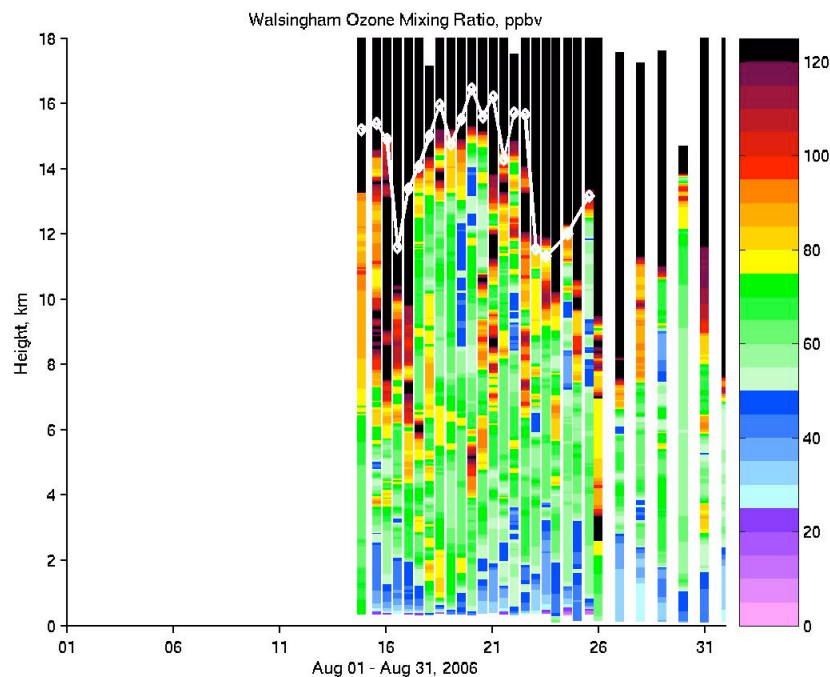

# Composite of Houston/RV Brown profiles echo Huntsville UT behavior

3/21/2007

IONS 2007 Data Workshop

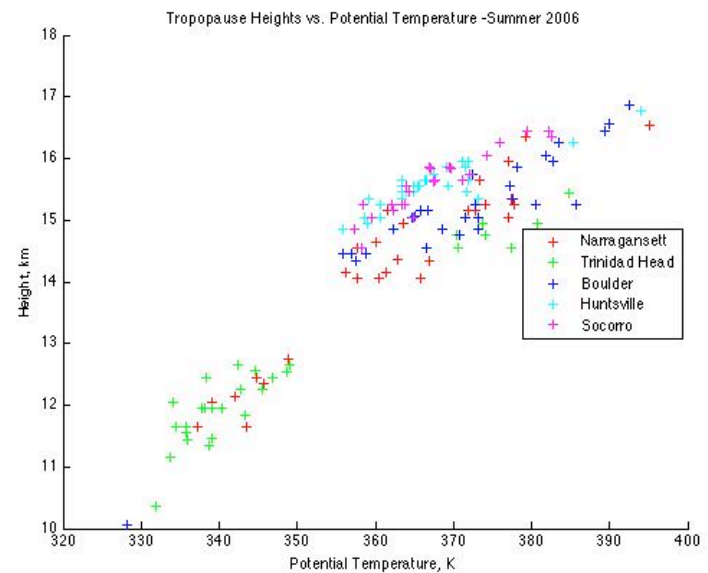

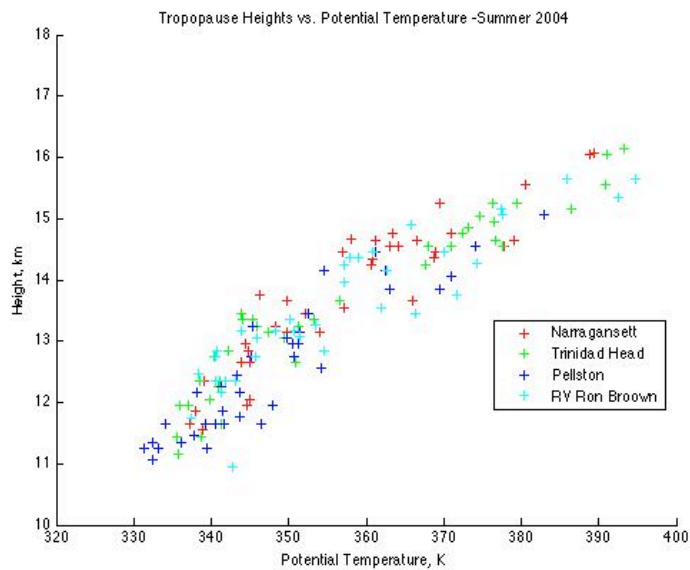

# Sub-synoptic variability revealed by twice-daily profiles

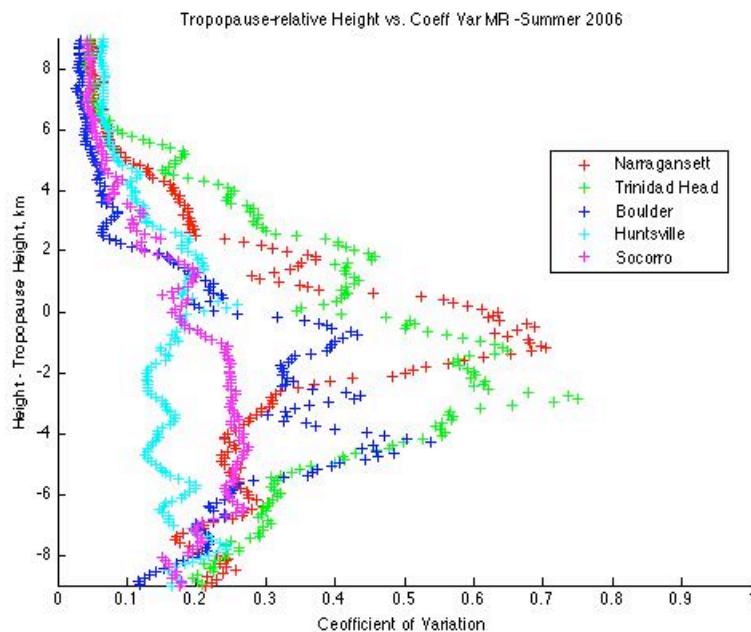

- Mesoscale variability throughout troposphere
- Numerous abrupt shifts
- Frequent deep, clean surface layer

# Tropopause phenomena

## Height of thermal tropopause vs. $\theta$

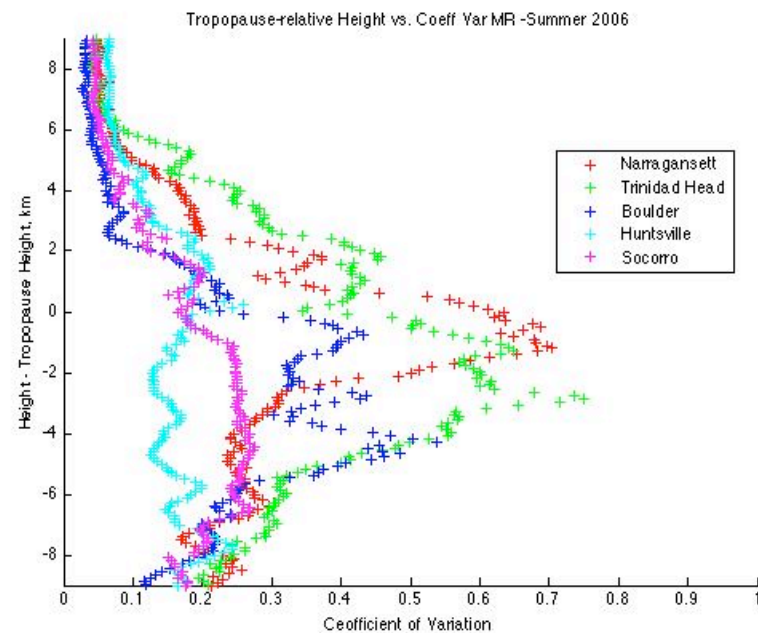

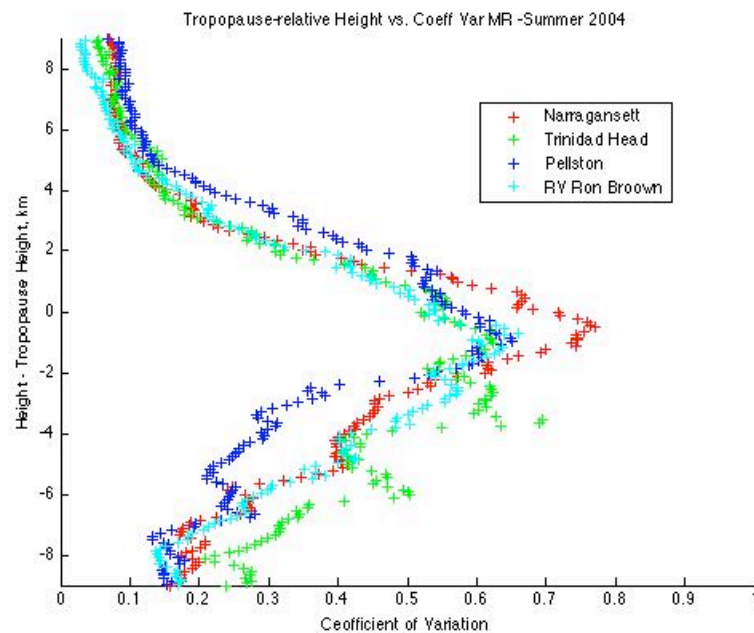

# O<sub>3</sub> mixing ratio variability near tropopause

- Height relative to tropopause vs. coefficient of variation, here about monthly mean.
- Notable intra-site differences
- Mid-tropospheric and mid-stratospheric variability minima

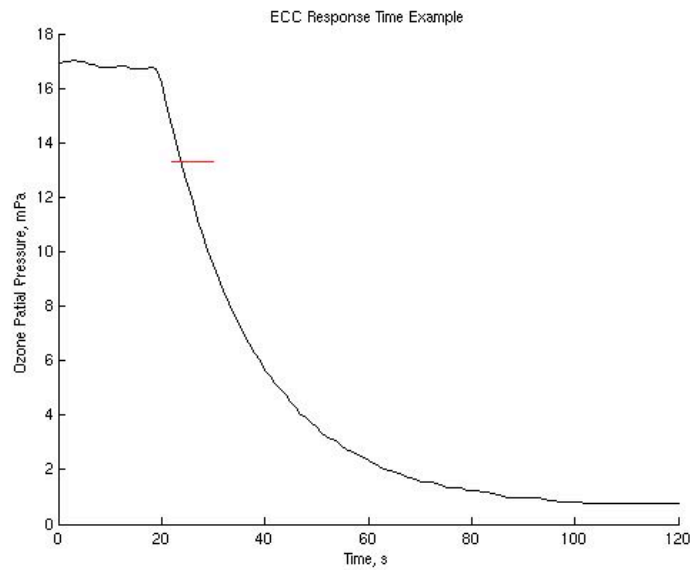

# Near-tropopause variability - 2004/2006 comparison

3/21/2007

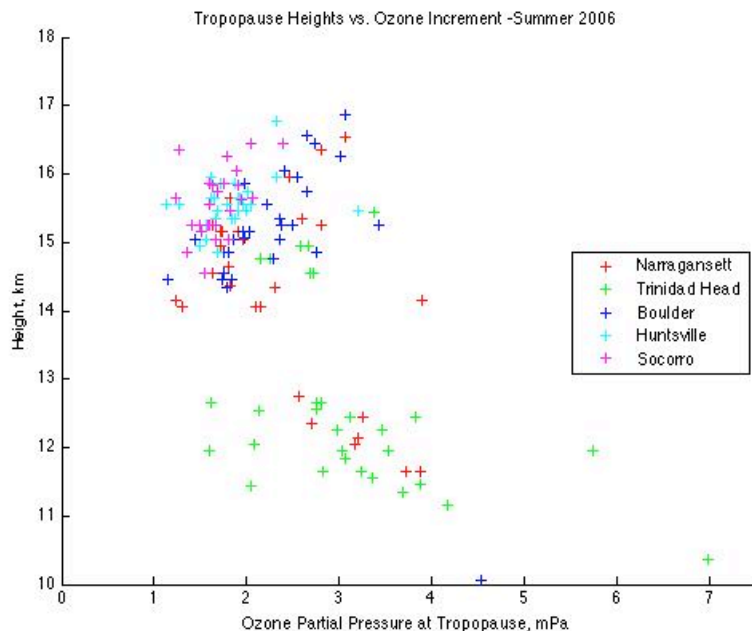

IONS 2007 Data Workshop

# Response time of ECC sonde

- Time to  $e^{-1}$  response typically 22-28s.
- 3 RT x Ascent rate  
~350 m
- Effects not accounted for in typical analysis.
- Asymmetric response - a long tail for  $\delta O_3 < 0$ .

# Underestimate of tropospheric column - crude, lag-displacement analysis

- $O_3$  partial pressure averaged over 300 m above thermal tropopause.
- Shown for summer, 2006 profiles at several sites.
- Summer, 2004 data cover wider range, higher values.
- Absence of height dependence is notable.

## Effects of RT on column and variability estimates

- Column amounts minimally impacted for layers that are symmetrically distributed.
- Variability systematically underestimated because maxima and minima unreachable except for broad features (such as the stratospheric maximum).
- The underestimate is likely greatest near the tropopause.
- Relative impact of asymmetrical response effect is unknown.

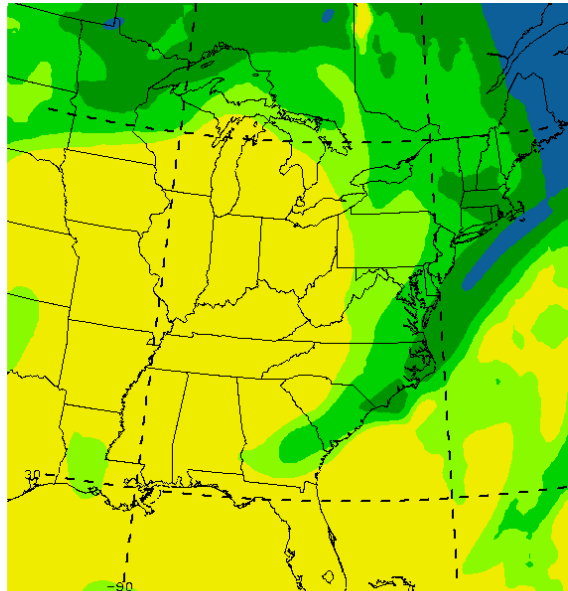

# Use of synoptic classification to group profiles for statistical analysis

...	BL	NA	...	•Some profile characteristics related to circulation.

# Lamina-labeling approach to source attribution

- Lamina-labeling technique apportions tropospheric ozone to sources including stratosphere based on analysis of layers.
- Layers in profiles with adequate static stability associated with stratospheric wave breaking and other sources using  $\theta$ ,  $O_3$  correlations.
- Wave breaking events leading to laminae are large-scale occurrences.

# Going beyond lamina labeling

- Laminae discernable in high-resolution synoptic rawinsonde data as well, in  $\theta$ ,  $U$  correlations.
- $O_3$  rich air in laminae accompanied by PV, shown here at  $\theta$  347.5 K.
- Accidental Lagrangian analysis of distribution and evolution of laminae seems justified.
